Automation technology can aid in software design to reduce program errors, written code, application response times, and user interaction with systems. As the level of automation becomes higher, the cost of software development also decreases. The software that is developed from automated design is called Automated Software Engineering (ASE). Without automation, software design and development can be extremely time consuming and expensive. In ASE, automated design tools are used to generate design information from which the automated tools generate the source code. Automated tools are able to maintain much of the design information, which has improved software reliability and reduces design time and costs. To date, most tools that are used to generate the source code are stand-alone tools. However, the stand-alone tools are inefficient because they are unable to share design information. In ASE, automated tools are utilized to design and develop software from design information. These tools are often incorporated into development environments that are used for the coding of software. Prior Art FIG. 1 illustrates a simplified CAD system that includes a development environment where a development tool is operated. In this example, the development environment includes a CAD tool 100, a design management tool 101, and an execution tool 102. CAD tool 100 is configured to generate and edit the design information. Design management tool 101 is configured 570a42141b
