assumption. Qed. Increased peri-operative myocardial infarction in patients undergoing hepatic surgery. We hypothesized that  
hepatic surgery is associated with an increase in peri-operative myocardial infarction (MI), independent of atherosclerotic risk  
factors. This study evaluated the frequency of peri-operative MI in patients undergoing hepatic resection. We studied 912  
consecutive patients undergoing hepatic resection. The overall complication rate was 32.5%. Mortality after hepatic resection  
was 7.5%. MI occurred in 8.8% of patients, more frequently in those undergoing major hepatic resection (9.8%) than in those  
undergoing minor resection (2.8%) (p=0.003). For patients undergoing hepatic resection, MI is associated with male gender  
(odds ratio, 2.7; 95% confidence interval 1.5-4.8), major resection (odds ratio, 4.5; 95% confidence interval 2.2-9.2), DM (odds  
ratio, 2.8; 95% confidence interval 1.3-5.8), obstructive coronary artery disease (odds ratio, 2.4; 95% confidence interval  
1.2-4.7) and not being anemic at baseline (odds ratio, 2.0; 95% confidence interval 1.2-3.2). Intra-operative myocardial  
ischemia occurred in 18.5% of patients undergoing hepatic resection (p=0.
