Unilever to buy \$3.1 billion of home appliances from Toms shoes - plus ===== moJoe Unilever is supposedly the largest company in Europe, by far. While it is true that there's a tiny bit of decrease in the Dow Jones, Unilever is a huge company with more than \$23 billion in annual revenue and more than \$5 billion in market cap. I'm pretty sure this deal is a "no-brainer" for investors. Variability of patellofemoral contact kinematics in different directions of lateral patellar dislocation. To investigate the variability in patellofemoral contact kinematics in different directions of lateral patellar dislocation. Three-dimensional kinematic data from 14 dynamic patellofemoral contact (PC) assessments were used to analyze the response to lateral patellar dislocations (LPD). Data from 13 static PC assessments were collected and analyzed as a validation study. PC kinematics were analyzed by several measurements to obtain the lateral excursion of the lateral femoral condyle in three separate ways: (1) measured by the lateral distance between the articular surface of the lateral femoral condyle and the patella, (2) the lateral distance between the articular surface of the lateral femoral condyle and the articular surface of the patella before PC peak contact, and (3) the lateral distance between the articular surface of the lateral femoral condyle and the articular surface of the patella at maximum PF contact. These measurements were performed in different directions of LPD in five subjects. The largest amount of lateral patellofemoral movement occurred in the direction of the dislocation of the patella. The largest excursion values were found for the lateral distance from the femoral condyle to the patella before PC peak contact in all directions of LPD. The largest excursion of the lateral femoral condyle in response to all directions of LPD occurred at the maximum PC contact. These findings indicated a bias that may occur when using lateral distance measurements as a tool to detect PF contact in patients with LPD. In addition, the variability in patellofemoral kinematics in different directions of LPD can be explained by differences in

Bone is comprised primarily of calcium phosphate, which is a non-crystalline inorganic compound. Its chemical composition is about 60 wt% calcium phosphate and 40 wt% carbonate. However, bone, which is mechanically weak and is difficult to be shaped and adapted to a desired shape, has a complicated structure which includes cellular components such as collagen and bone marrow in addition to calcium phosphate. Moreover, calcium phosphate is quite chemically inert; a bone of a living body has been maintained under the aforementioned environment only by its highly developed bone forming ability and continuous blood supply in combination. In the recent years, interest in the role of calcium phosphates in biomineralization has drawn attention since it is recognized that calcium phosphates play an important role in the growth of bones and teeth. Inorganic calcium phosphates may occur in the form of various crystal structures. Among them, the most common ones are $\text{Ca}_{10}(\text{PO}_4)_6\text{X}_2$ (X represents Cl, OH, NO_3 or SO_4), referred to as apatite, and $\text{CaHPO}_4 \cdot 2\text{H}_2\text{O}$ or whitlockite, referred to as brushite. Whole bones and teeth can be considered as products of a process of biomineralization. Bones grow by an accumulation of minerals including calcium phosphate. These minerals are usually deposited in the form of calcium phosphate apatite. During this process, bones and teeth initially form amorphous calcium phosphate which then crystallizes into apatite. The amorphous calcium phosphate and apatite are accompanied with a mass of organic substances which are eventually dissolved. The bones and teeth can be regrown through a continuous process of re-mineralization by the so-called "remodeling." Furthermore, it is known that calcium phosphate is also used as a starting material to make, for example, artificial tooth. Recently, there are growing demands for various medical instruments and implants, which can be implanted in a body in combination with a biologically active substance such as a bone-forming agent and/or a living cell or tissue. More specifically, there are increasing demands for medical instruments and implants which can be readily implanted in a body by such a simple method as merely pushing a medical instrument or an implant in a body by using a rod, wire or needle. For this purpose, materials which are highly compatible with living tissues and provide their permanent shape and form should be
