Previous investigations by this applicant and others have provided evidence for the involvement of O6-methylguanine-DNA methyltransferase (MGMT) in the biological defense of cells against O6-alkylguanine alkylating agents. MGMT is the major enzyme responsible for repairing these lesions, catalyzing the transfer of the alkyl group to the cysteine on the active site of the enzyme. This transfer occurs in a reversible fashion and results in the restoration of the alkyl group to the O6 position of guanine. Once attached to guanine, the alkyl group is very labile and is readily cleaved from the DNA by cellular repair enzymes. In wild-type MGMT, the attached alkyl group is repaired in about one-half of cellular DNA. In mutant forms of the enzyme, however, the repair process is either deficient or non-existent, allowing the alkyl group to persist on DNA and to be readily attacked by hydrolytic enzymes. Because of the essential role that MGMT plays in the repair of O6-alkylguanine, its mutation or deletion leads to resistance to the effects of alkylating drugs. Several clinical studies have shown that patients who are deficient in MGMT, resulting from either inherited mutations of the enzyme or loss of heterozygosity due to its loss of gene function, are better responders to chemotherapeutic regimens that contain alkylating agents.
