Razer ThunderStick Sound Bar Stand iSAMSQ: Project optimization and source control I am working on a project of my own, and I have a question regarding project optimization and source control. To my understanding, source control is important to be able to check out code changes with ease and then quickly check code changes before submitting them. However, in my case, all changes I make are made via a GUI. Since my code changes are made by hand, I can usually control the order and point of changes, and am able to use git's ability to check in changes by commit order. I would like to do a build for a long-running project, such as a project of mine which has an application written in C++ that will be running for a few years, so I want to know if it would be best to create a temporary build configuration or a manual checkout with the current build configuration. For example, I could create an environment in which I can only check code changes in by commit order, and then after a certain point in time, the build will be shut down and built again. Or, I could create a build configuration with everything, then update the

environment to update only one part of the code which I need to build. I understand that, in some cases, I may have to switch between configurations for various reasons, and that I should try to keep them as close as possible to the same configuration, but what would be the best practices? A: (I'll post this as an answer, since I'm not sure if I can use a comment. And I don't want to clog up the comments.) I think f988f36e3a
